## Wide bandwidth analog switch IC

### ■ Overview

The AN5870K is a wide bandwidth analog switch IC of 300 MHz operation. It is usable for RGB signal and horizontal/vertical synchronizing signals, and it has a built-in 75  $\Omega$  driver for video signal. In addition, it has also realized a high speed operation by the adoption of CMOS process for its sync. signal processing circuit. It is usable in a broad range from a popular type monitor to a high definition monitor.

### ■ Features

- 2-input 1-output circuit (DC switch type)
- Built-in 6 dB amplifier for RGB signal (1.5 dB for 75  $\Omega$  termination)
- Built-in sync. separation circuit (Supporting sync. on green and power save)
- Higher speed horizontal / vertical sync. signal circuit ( $t_{\text{delay}} = 20$  ns)

### ■ Applications

■ Technical Information

• Operational explanation

1. SW block

Switches over R, G, B, H, V signal of 2 systems.

SW pin (pin 22)	Selected pins
In low-level	R in 1 (pin 1), G in 1 (pin 5), B in 1 (pin 9), H in 1 (pin 13), V in 1 (pin 15)
In high-level	R in 2 (Pin 3), G in 2 (pin 7), B in 2 (pin 11), H in 2 (pin 14), V in 2 (pin 16)

2. High-level signal detection block

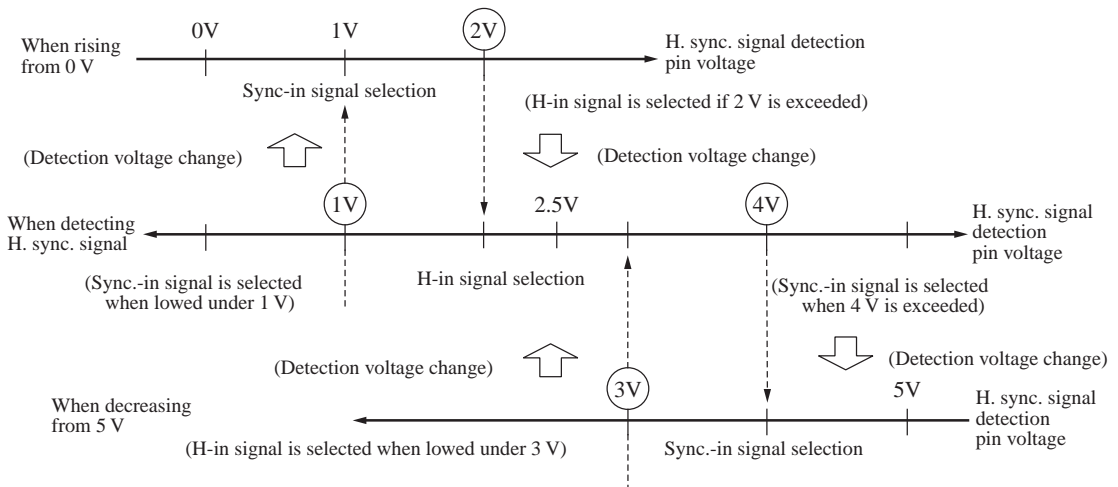

Sync.-in pin (pin 21) is a pin for inputting the sync.-on green signal and it is separated into the composite sync. signal (composite sync.) inside. H-in 1 and 2 pins (pin 13 or pin 14) are input pins for the video signal and the separated horizontal signal.

The high-level signal detection block discriminates the presence of H-in signal which is selected in SW block and provides the output to H-out pin (pin 19) in the following manner.

Input signal		Output signal
Sync.-in pin (pin 21)	H-in pin (pin 13 · pin 14)	H-out pin (pin 19)
●	●	H-in signal
●		Sync.in signal
	●	H-in signal
		DC (state of sync.-in pin)

H signal detection pin (pin 20) voltage becomes under 1 V or over 4 V if H. sync. signal is not inputted.

The output signal for the H. sync. signal detection pin voltage becomes as follows and it has hysteresis characteristics. It is possible to adjust the H. sync. signal detection time by means of an external capacitor.

■ Usage Notes

1. About C22 0.01 μF capacitor (refer to ■ Application Circuit Example)

In the case of evaluation board for this IC without heat sink, a resonance phenomena takes place at approx. 400 MHz between pin 23 B-out pin and pin 22 SW pin and affects the frequency characteristic of B-out pin.

To solve the above problem, the correction can be made by attaching C22 0.01 μF capacitor between pin 22 SW pin and GND at a place as close to the IC as possible.

In the case of using this IC, study if the correction is necessary.

2. About latch-up

In our latch-up testing, a voltage charged to 200 pF capacitor is applied to the IC pin, in the state of providing only a voltage to the power supply pin of the IC, and we confirm that the latch-up does not occur up to 200 V.

It is confirmed that this IC does not cause latch-up up to 200 V under a condition including the peripheral components. (Refer to ■ Application Circuit Example).

Be careful to pin 20, pin 21, pin 28 and pin 30 which are especially weak.

In the case of using this IC, the peripheral components to be attached externally should be placed as close to the IC as possible.
